ABSTRACT
Aims and objectives: To determine the prevalence of pulmonary tuberculosis among respiratory symptomatic subjects in an out-patient primary health unit.

Methods: A prospective study was conducted in the department of pulmonary medicine, Rohilkhand Medical College and Hospital, Bareilly. The suspected patients were subjected to a complete set of detailed history and examination. Socio-demographic data were collected during the history examination. The RSI (respiratory symptomatic individuals) provided sputum specimens for detection of acid fast bacilli. The patients sputum was examined under a fluorescent microscope using an auramine rhodamine stain in the RNTCP certified designated microscopy centre(DMC) laboratory by the experienced lab technicians.

Results: Among the 110 patients with reported respiratory symptoms studied for more than two weeks were enrolled into the study from November 2014 to November 2015. Amongst the cases studies 30 individuals reported positive for AFB (acid fast bacilli) on sputum smear microscopy.

Conclusions: The prevalence of pulmonary tuberculosis is high in the rohilkhand region. The patients who present with the respiratory symptoms esp. with the cough with expectoration for more than 2 weeks with lesions on the chest x ray should be considered for pulmonary tuberculosis on priority basis so as to initiate the treatment as soon as possible and to minimize the risk of spread of the infection.

KEYWORDS: Prevalence, Active case finding, Tuberculosis, Pulmonary tuberculosis, Respiratory symptomatic.

INTRODUCTION
Tuberculosis continues to be a major cause of morbidity and mortality worldwide. There are an estimated 8.8 million incident cases of tuberculosis globally. India has the highest burden of TB in the world, an estimated 2 million cases annually. This accounts for approximately one fifth of the global incidence of TB. It is estimated that about 40% of the Indian population is infected with TB bacteria. The vast majority of infected people have latent TB rather than active TB disease. It is also estimated by the World Health Organisation (WHO) that 300,000 people die from TB each year in India. For the 12th five year plan for 2012 – 2017, the vision of the government was for a TB free India, through achieving Universal Access by provision of quality diagnosis and treatment for all TB patients in the community.

The overall budget required in 2012 – 2017 to achieve this Universal Access vision, to save 750,000 lives from TB, and to control MDRT TB, was estimated to be Rs. 5825 crore ($1.17 billion) over the period 2012 – 2017.

The bacterium that causes TB is called Mycobacterium tuberculosis. Inactive tuberculosis means that one can even unconsciously and unknowingly acquire the bacteria for tuberculosis within them but not even know about it because it is inactive. Whereas, active tuberculosis is the start of the bacteria developing, and the signs and symptoms begin to be visible. This is when tuberculosis is active within a person, and is a serious issue leading to even more serious results. Although the TB bacteria can infect any organ (e.g., kidney, lymph nodes, bones, joints) in the body, the disease commonly occurs in the lungs.

Common symptoms include:
- chills
- chest pain
- shortness of breath
- loss of appetite
- coughing that lasts longer than 2 weeks with green, yellow, or bloody sputum
- weight loss
- fatigue
- fever
- night sweats

Systematic screening for active TB is defined as the systematic identification of people with suspected active TB, in a predetermined target group, using tests, examinations or other procedures that can be applied rapidly. Among those whose screening is positive, the diagnosis needs to be established by one or several diagnostic tests and additional clinical assessments, which together have high accuracy. Systematic screening in high risk groups is a possible complement to efforts to improve the patient-initiated pathway to TB diagnosis (that is, diagnosing TB among people who actively seek care with TB symptoms, also called “passive case-finding”).

Estimating the burden of respiratory symptomatic individuals (RSI) and pulmonary TB in the prison system is important to determine fund allocation in this high-risk setting. The main objective of this study was to determine the prevalence of RSI and possible predictors associated with them, and the rate of pulmonary TB through active case finding (ACF) in suspected patients of tuberculosis.

MATERIALS AND METHODS
The study was conducted on patients reporting at the Department of Pulmonary Medicine at OPD / IPD clinic in the Bareilly district. Staining was done in the DOTS/ Microscopy centre of the Department of Pulmonary Medicine, Rohilkhand Medical College, Bareilly. The Institutional Ethical Committee permission was taken. 2 sputum samples i.e. one spot and one morning sample were taken from patient for smear examination. The duration of study was one year i.e. from November 2014 to November 2015.

After collecting spot sample, individuals were provided with pre-labeled sample containers for the collection of morning sample at home. New unscratched slides labeled with study numbers were used for smear preparation. The smears were stained by Ziehl Neelsen and Auramine O staining. Ziehl Neelsen and Auramine O staining technique
and smear gradings were done as per RNTCP Technical Manual Guide-lines as mentioned in the table below.

| LED fluorescent microscopy(400xc:1 length =40 fields=200 HPF) | IUALTO/WHO scale (1000x field = HPF) grading | Minimum number of fields to be examined Minimum number of fields to be examined

*as mentioned in the manual for sputum smear Fluorescent micro-copy(RNTCP)*.

The prevalence of RSI and pulmonary TB were calculated and associ-ations with potential predictor variables were assessed with the chi-square test when appropriate, and multivariate logistic regression was used to assess the independent effects of each covariate. Data were analyzed using SPSS (v.12.0, SPSS Inc, Chicago, IL, USA).

**Results**

Between November 2014 to November 2015, a total of 110 patients were studied and were included in this study. Their median age was 27 years (range: 18–67 years old). Patients included in the study were classified into for age, race, marital status, education, employment.

Among the 110 patients, 90 patients had reported respiratory symp-toms for over 2 weeks. All patient who had no resolution of their res-piratory symptoms following broad-spectrum antibiotic therapy pro-tected. They were then asked to sign the written consent form. For the first step, patients reporting cough for over 2 weeks were en-rolled.

The review showed that rural residence was an important determi-nant of patient delay in seeking and receiving care for TB. Programs such as DOTS have proven successful in detecting and treating TB infection in India. However, concerns have been raised regarding the impact of such programs on the most vulnerable members of the populations, particularly the rural poor population. In spite of the pro-gress made by TB control programs, “the prevalence of active PTB in India, has in fact, increased”. Thus, greater focus on equitable distri-bution of TB-related resources and improved targeting of vulnerable rural populations is of central importance in the control of TB.

Another cultural aspect of TB diagnosis and treatment delay is the stigma that is attached to the disease, which drives individuals to hide their condition from others, thus hindering them from access-ing available diagnosis and treatment services. One study which fo-cused on public awareness about TB concluded that approximately 72% of respondents held some stigmatizing attitudes towards the disease. Increasing public knowledge and awareness of TB as a dis-ease that can be diagnosed and successfully treated if detected early is important for TB control efforts in the country. Available evidence shows that interventions to reduce the TB stigma can be effective if designed to empower individuals with TB to resist stigmatizing judg-ments, while working to change norms about the disease.

**Conclusion:**

TB symptoms should be better explained to the population and healthcare professionals should be better trained to both reduce such delays and initiate treatment as early as possible. Patient and diag nostic delays in TB care are mediated by individual and health facility factors. Population-based interventions that seek to reduce TB stigma and raise awareness about the benefits of early diagnosis and prompt treatment are needed. Policies that remove patients’ financial barriers in access to TB care, and integration of the informal care sector into TB control in urban and rural settings are central factors in TB control.

The prevalence of pulmonary tuberculosis is high in the Rohilkhand region. The patients who present with the respiratory symptoms esp. with the cough with expectoration for more than 2 weeks with lesions on the chest x ray should be considered for pulmonary tuber culosis on priority basis so as to initiate the treatment as soon as pos-sible and to minimize the risk of spread of the infection.
