ABSTRACT

Pregnancy, the period from conception to birth, is characterised by profound hormonal changes. The tissues supporting the teeth, including the periodontium especially gingiva is affected. There are several reasons why dental professionals should focus on oral health in pregnant women. This article focus light on some of these oral diseases.

INTRODUCTION

It is increasingly recognized that oral health plays an important role in general health and well-being, many women do not visit a dentist before or during pregnancy, even when there are obvious signs of oral disease. A major entryway into the body, the mouth can become a source of disease or pathological processes affecting other parts of the body. Oral health problems are common in pregnant women. Improving the oral health of pregnant women prevents complications of dental diseases during pregnancy. Recent studies have reported associations between oral diseases, particularly periodontal disease, and an increased risk for poor birth and pregnancy outcomes such as preterm birth, low birth weight. Periodontal disease results in appearance of inflammatory markers in the bloodstream which are also thought to have a role in the onset of labour. Adaptation to the physiological changes during pregnancy includes dietary changes such as increased craving for particular foods and a higher frequency of snacks between meals. To maintain good oral health during pregnancy, dental care and special home management is required. It is safe to deliver oral health services during the perinatal period, and delaying necessary treatment could result in harm to the mother and indirectly to the fetus.4,5

Oral diseases associated with pregnancy

a) Dental Caries

There is much debate about whether the risk for dental caries is increased in pregnancy. Some changes in caries risk behaviour may occur, but they would need to be substantial and maintained over a long period to have an impact on dental caries rates. Behaviours that may occur and have impact on caries risk are craving for and eating sugary foods and frequent ingestion or use of carbonated drinks to alleviate nausea.6

b) Gingival and periodontal disease

Gingivitis in pregnancy is caused by bacterial plaque. Pregnancy accentuates the gingival response to plaque and modifies the resultant clinical picture. These changes may increase susceptibility to oral infections and hinder the body's ability to repair and maintain soft tissues within the mouth. During pregnancy, reversible mild inflammation of the gums, called “pregnancy gingivitis,” is estimated to occur in 30 to 100 percent of pregnant women. 9 Pregnancy gingivitis usually appears in the first trimester of pregnancy. This form of gingivitis results from increased levels of progesterone and estrogen causing an exaggerated gingival inflammatory reaction to local irritants.10

Untreated gingivitis can lead to periodontitis, believed to affect 5 to 20 percent of pregnant women. Periodontitis can erode the bone and other supporting structures of teeth resulting in tooth loss. Pyogenic granulomas, pregnancy tumors, or pregnancy epulides occur in 0.2% to 9.6% of pregnancies. They are clinically and histologically indistinguishable from pyogenic granulomas occurring in women who are not pregnant or in men. They appear most commonly during the second or third month of pregnancy. The lesion classically occurs in an area of gingivitis and is associated with poor oral hygiene and calculus. 11

Tooth mobility is a sign of periodontal disease caused by mineral changes in the lamina dura and disturbances in the periodontal ligament attachments. Vitamin C deficiency contributes to this problem, so the patient should be advised accordingly. Removal of local gingival irritants, therapeutic doses of vitamin C and delivery typically result in reversal of the tooth mobility. 12

c) Infection

Odontogenic infection during pregnancy have adverse outcomes thus, should be treated promptly. As such, there is a decrease in cell-mediated immunity and natural killer cell activity during infections; hence infections need to be controlled at the earliest. Abscesses should be drained and the offending pulp extirpated or the tooth should be removed to control the infection.10

d) Dental Erosion

Nausea and vomiting are the commonest symptoms consistently experienced in early pregnancy. Surveys report that nausea with or without vomiting affects about two-thirds of pregnant women, with up to 80% of these experiencing some nausea, 9.2% experiencing nausea and vomiting for most of the pregnancy (Louik et al. 2006).13 Persistent vomiting may have an erosive effect on tooth structure, and pregnant women should be advised to have a drink of milk or water following a vomiting episode and not to brush their teeth immediately after vomiting.14
INSTRUCTIONS TO BE FOLLOWED DURING PREGNANCY15

**INDICATIONS** | **RADIOGRAPHS** | **ANALGESICS(with FDA Category*)** | **LOCAL ANESTHETIC (with FDA Category*)** | **AMALGAM PLACEMENT OR REMOVAL** | **NITROUS OXIDE** | **ANTIBIOTICS & ANTINFECTIVES (with FDA Category*)**
---|---|---|---|---|---|---
Anytime during pregnancy | Diagnostic x-rays are safe during pregnancy Use neck (thyroid collar) and abdomen shield | Acetaminophen (B) Can Specitaline (B) Morphine (B) Codeine (C) Acetaminophen + Morephine (C) Acetaminophen + Hydrcodone (C) Acetaminophen + Oxycodone (C) | No evidence that the type of mercury released from existing fillings harms the fetus Use rubber dam and high-speed evacuation to reduce mercury vapor inhalation | 30% nitrous oxide can be used when the topical or local anaesthetics are inadequate Pregnant women require lower levels of nitrous oxide to achieve sedation | AVOID: Metronidazole (B)

1st Trimester (1-13 WEEKS) | Spontaneous pregnancy loss occurs in 10-15% of all clinically-recognized pregnancies in the first trimester. Most losses are due to chromosome abnormalities. Yet, women may prefer to wait until the second trimester (14th week) for dental care. | AVOID: Naprosyn (B)

2nd Trimester (14-27 WEEKS) | NEVER USE NSAIDs e.g. Ibuprofen or Indomethacin | AVOID: Sulfonamides (C)

3rd Trimester (28-40 WEEKS) | NEVER USE Aspirin unless prescribed by the prenatal care provider **Caution:** Consult with prenatal care provider before recommending Ibuprofen (B) or Naprosyn (B) during the 1 and 2nd trimesters | Caution: Consult with prenatal care provider if using anesthesia other than a local block e.g. IV sedation or general anesthesia | NEVER USE Tetracyclines (D) | Erythromycin in estolate form

*Cat B: No evidence of risk in humans; either animal studies show risk (human findings do not) or, if no adequate human studies done, animal findings negative.

*Cat C: Human studies are lacking and animal studies are either positive for fetal risk or lacking as well; potential benefits may justify the potential risk.

*Cat D: Positive evidence of risk. Investigational or post marketing data show risk to fetus. Nevertheless, potential benefits may outweigh the risk.

**Prevention of oral disease in pregnancy**

Standard preventive measures such as drinking of fluoridated water, twice daily use of fluoridated toothpaste and a low-sugar diet should be recommended for pregnant women (Griffin et al. 2007; Yeung 2007).16 Fluoride supplements are not recommended in pregnancy as there is no evidence of effectiveness. A visit to the dentist is recommended for all pregnant women to check on periodontal conditions, as well as to minimise cariogenic oral flora through treatment of existing dental caries and maintenance of oral hygiene habits. Plaque control through meticulous oral hygiene is suggested for minimisation of gingivitis and to reduce the load of oral bacteria. Smoking cessation advice should be part of a preventive strategy for periodontal disease and for the range of conditions with which periodontal disease has been associated.

**Dental treatment in pregnancy**

Other than good plaque control, it is prudent to avoid elective dental care if possible during the first trimester and the last half of the third trimester. The first trimester is the period of organogenesis when the foetus is highly susceptible to environmental influences. In the last half of the third trimester, a hazard of premature delivery exists because the uterus is very sensitive to external stimuli. Prolonged chair time may need to be avoided because the woman is most uncomfortable at this time. Further, supine hypotensive syndrome may possibly occur. Supine hypotensive syndrome can usually be reversed by turning the patient on her left side, thereby removing pressure on the vena cava and allowing blood to return from the lower extremities and pelvic area. A preventive 6-inch soft wedge (rolled towel) should be placed on the patient's right side when she is reclined for clinical treatment. The American academy of Periodontology has developed a position statement regarding the need for proper treatment in pregnant patients.17

It is most desirable not to have any irradiation during pregnancy, especially during the first trimester, because the developing foetus is particularly susceptible to radiation damage. When radiographs are needed for diagnosis, the most important aid for the patient is the protective lead apron. Drug therapy in the pregnant patient is controversial because drugs can affect the foetus by diffusion across the placenta. Ideally, no drug should be administered during pregnancy, especially the first trimester. Usually, there is a risk that the drug can enter breast milk and be transferred to the nursing infant, in whom exposure could have adverse effects. The mother should take prescribed drugs just after breastfeeding and then avoid nursing for 4 hours or more, if possible, to markedly decrease the drug concentration in breast milk.7A recent clinical trial by Michalowicz et al. (2008)18 found that providing dental treatment between 13 and 21 weeks gestation was not associated with any adverse pregnancy outcomes. The treatment provided included scaling and root planning with local anaesthesia, and emergency dental treatment including restorative and surgical care. This supports work by Daniels et al. (2007)19 who found that dental care during pregnancy, including amalgam fillings, was not associated with adverse birth outcomes.

**Conclusion**

Oral health is very important during pregnancy and can be provided safely and effectively. Dentists need to play a proactive role in the maintenance of the oral health of pregnant women.
lar dental visits are important to diagnose any dental disease at an initial stage. Paying attention to the physiologic changes associated with pregnancy, prescribing medications on the basis of drug safety categories and management of oral infection appropriately are important considerations.
