ABSTRACT

PURPOSE: To study ocular manifestations of dengue hemorrhagic fever and its association with platelet count

METHODS: Cross sectional observational study of 30 patients was done at PBM hospital, Bikaner. IgM and IgG positive dengue cases were selected over 4 months period. Ocular and systemic examination was carried out during hospitalization and follow up visits

RESULTS: From 30 patients 25(83.3%) were males and 5(16.7%) were females. Mean age was 32 years. Ocular manifestations were present in 19(63.3%) patients from which 15(50%) patients had petechial subconjunctival hemorrhage and 5(16.7%) patients had dot, blot hemorrhages and macular edema. All 16(53.3%) patients with platelet count of <35,000/µl had ocular manifestations. Ocular changes resolved in all the cases after 6 weeks.

CONCLUSION: Incidence of ocular complications in dengue is increasing hence all patients should be referred to ophthalmologist to prevent any sight-threatening complications.

Introduction

Dengue is self-limiting common arthropod-borne viral disease which is transmitted to humans by mosquitoes. It is endemic in tropics and warm temperate regions of the world. It is caused by 4 antigenically similar but immunologically distant serotypes of dengue virus of genus flavivirus, transmitted by Aedes Aegypti mosquito. Highest incidence occurs in South Asia and American tropics.1

Dengue infection is characterized by an abrupt onset of fever along with symptoms of malaise, sore throat, rhinitis, cough, headache, muscle ache, retro-orbital pain, lumbosacral pain, and rash. Other clinical manifestations of dengue are related to the bleeding diathesis from thrombocytopenia.2

A myriad of ocular manifestations ranging from mild subconjunctival hemorrhage to vision threatening complications such as optic neuropathy and panophthalmitis has been reported in literature.3-9 The main ocular manifestations included conjunctival hemorrhages, macular edema and retinal hemorrhages. Less common features included exudative retinal detachment, anterior uveitis, periphlebitis, branch retinal vein occlusion, and vitreous hemorrhage. A majority of patients were reported to have retro-orbital pain that can be due to sinusitis or due to myalgia. Visual impairment occurs secondary to maculopathy and optic neuropathy.5,8 The main objective of this study was to evaluate the ophthalmic manifestations associated with dengue hemorrhagic fever.

Materials and Methods

A cross sectional observational study was conducted in 30 patients of dengue hemorrhagic fever, who were admitted in Sardar Patel Medical College and PBM hospital, Bikaner (Rajasthan) India. The study was carried out for a period of 4 months from September 2016 to December 2016. Diagnosis was made by physician on basis of characteristics clinical signs and symptoms. It was confirmed by using dengue IgM and IgG capture ELISA test. After Informed consent, a detailed clinical history including systemic and visual complaints was taken. Patients underwent complete ophthalmic examination including visual acuity testing, anterior segment examination by slit lamp and posterior segment examination by direct and indirect ophthalmoscope and 90D lens.

Patients with ocular findings were called for weekly follow up upto 6 weeks in ophthalmology clinic after they were discharged from the hospital.

Result

Of the 30 patients diagnosed with dengue, 25(83.3%) were males and 5(16.7%) were females. Mean age was 32 years (20–60 years). All patients presented with fever while 28 (93.3%) patients also had myalgia. Other uncommon systemic findings were vomiting, lumbosacral pain and bleeding gums. Retrobulbar pain was present in 8 (26.7%) patients. Marked thrombocytopenia <50,000/µl was found in 26 (86.7%) and all patients with thrombocytopenia <35,000/µl had ocular manifestations with maximum in range between 15,000/µl and 35,000/µl.

The mean time interval of presentation of ocular features was eighth day with range of 5–11 days. Ocular findings were present in 19 patients; of which 17 (56.7%) had subconjunctival hemorrhage [Figure 3] as the most common anterior segment finding and 4 patients had conjunctival chemosis. Subconjunctival hemorrhage was either petechial type (15 patients) or diffuse type (2 patients).

Figure 1: Gender distribution

Posterior segment findings were present in 5 patients (16.7%), of which 2 (40%) had peripheral retinal hemorrhages, 2(40%) had hard exudates and 4(80%) had macular oedema. Complete resolution of ocular findings was noticed within 6 weeks in all the 19 patients who had ocular manifestations [Figure 2]. It was mainly attributed to the improving platelet count.

Ocular manifestations are usually seen 7-8 day after onset of fever. The spectrum of ophthalmologic manifestations would lead one to conclude that several pathophysiologic processes are involved. The first and most obvious pathogenesis would be the thrombotic state with its resultant bleeding tendency, which gives rise to increased incidence of hemorrhage. Another pathogenesis of DHE involves immune clearance by way of induction of cross-reactive T-cell memory, T-cell proliferation, and recognition of dengue viral antigens on infected monocytes by sensitized cytotoxic T cells. This results in the release of cytokines with vasoactive and procoagulant properties (interleukins, tumor necrosis factor, platelet-activating factor, and urokinase)11. Vasoactive and inflammatory mediators cause capillary leakage, which may form the basis for macular edema and conjunctival chemosis while breakdown of the blood aqueous barrier result in anterior uveitis and periphlebitis.

Our study is similar to that by Kapoor et al. and Hussain et al. with regard to male preponderance. The mean age group of our study is 32 years that is also similar in other studies.

Because there is expected increase in epidemicity of dengue fever, hence even the ophthalmic manifestations are expected to rise, so the treating physician should be aware and promptly refer any such case to the ophthalmologist as early as possible so that proper treatment can be given to prevent any vision threatening condition.
