CHRONIC KIDNEY DISEASE (CKD) is becoming a serious health problem; the number of people with impaired renal function is rapidly rising [1]. Chronic kidney disease includes a spectrum of distinct pathophysiological processes which is associated with abnormal kidney function and a progressive reduction in glomerular filtration rate[2,3]. CKD is a clinical syndrome which occurs due to irreversible loss of renal function leading to metabolic, endocrine, excretory and synthetic function resulting in accumulation of non – protein nitrogenous substances which leads to metabolic derangements and ends up with distinct clinical manifestations. End stage renal disease is described as a terminal stage of chronic kidney disease that without any replacement therapy patients could not survive would result in death. The thyroid hormones are essential for growth and development of the kidney and for maintaining electrolyte and water homeostasis. So excretion of iodine is reduced in advanced renal failure. Impaired renal clearance of iodine leads to elevated serum levels of inorganic iodide that potentially blocks thyroid hormone production resulting in “Wolff-Chaikoff” effect.

In current study we hypothesized that the thyroid abnormalities found in CKD patient. We conduct this study with objective to assess the probability of thyroid abnormalities In correlation with stage of CKD in tribal population who were admitted under nephrology unit, Dr. Bhimrao Ambedkar Hospital Raipur (C.G.)

MATERIALS AND METHODS
Patients who were admitted in the department of medicine under nephrology unit, Dr. Bhimrao Ambedkar Hospital Raipur (C.G.) between month of February to March 2018. The present study is conducted on total 60 patient, who were diagnose to have Chronic Kidney Disease. Ethical clearance has taken from the ethical committee of the Pt. JNM Medical College Raipur, prior to conduct the study. All participants and family members of the patients were provided written information consent. An approved pre-structured tools or format was used to collect the information that include basic parameters age, sex, pulse, blood pressure, Peripheral smear for anaemia, blood urea, Serum Creatinine ,Creatinine clearance (using Cockcroft — Gault formula) ,Serum electrolytes ,Serum calcium, phosphorous and uric acid, Serum cholesterol, 24 hours urinary protein, Serum protein (Total protein / albumin / globulin),USG abdomen for evidence of chronic kidney disease .After selection of patients, fulfilling the above criteria, about 5 ml of blood sample is collected in non-heparinised serum bottle and sent for thyroid profile test. Components of thyroid profile included in our study

THYROID ABNORMALITIES IN CORRELATION WITH STAGE OF CKD IN TRIBAL POPULATION OF CHHATISGARH

BACKGROUND
Chronic Kidney Disease is a worldwide health problem with an increasing incidence and prevalence. Abnormalities in the structure and function of the thyroid gland and in the metabolism and plasma concentration of thyroid hormones are common in patients with CKD. In view of variability of thyroid profile in CKD patients in previous studies, a prospective study of various thyroid function has been undertaken to establish a correlation if any between thyroid dysfunction and severity of renal diseases . Total number of 50 patients with Chronic Kidney Disease on conservative management fulfilling the criteria for CKD who were admitted in Department of Medicine under nephrology unit, Dr. Bhimrao Ambedkar Hospital Raipur (C.G.), during the period of February 2018-March 2018 were selected in this prospective study. The result showed that out of the 50 patients with CKD 29 patients had low T3 syndrome (0.2-2.0ng/ml, mean 0.67) which accounts for 58% of the patients, 12 patients had low T4 syndrome (0.5-8.5μg/ml, mean 5.65) which accounts for 24% of the patients and 4 patients had primary hypothyroidism TSH >20μIU/ml. Excluding Primary Hypothyroidism, analysis of serum T3, T4 and TSH in the study subjects shows very high significance, p < 0.001. Thyroid Dysfunction occurred in 66% of the patients with chronic kidney disease in our study, it does not indicate a state of hypothyroidism, but a reflection of the state of chronic illness/malnutrition. The low T3 state of CKD can be viewed as being protective, promoting conservation of protein. The number of patients with low T3 syndrome progressively increases with the severity of renal failure.
Among the 50 patients in our study, patients who were 25 years old and below were 7 constituting 14%, between 26 – 60 years were 38 constituting 78% and above 60 years of age were 5 in number constituting 10%.

Out of the patients, 33 patients had GFR of less than 15 ml/minute accounting to 66%, 15 patients had GFR ranging from 15-30 ml/minute accounting for 30% and 2 patients had GFR ranging from more than 30 ml/minute accounting for 4%. Among the patient studied most were in the range of creatinine clearance <15 ml/minute.

In our study out of 50 patient, 33 patients had low serum T3 levels (66%), 4 patients among low serum T3 value, they also had low T4 and high TSH suggesting primary hypothyroidism (8%). So excluding 4 patients of hypothyroidism 29 patients had low T3 syndrome in our study.

Out of 50 patients in our study 34 patients (68%) had the symptoms suggestive of hypothyroidism such as tiredness, weakness, cold intolerance, dry coarse skin, constipation, hoarseness of voice, loss of hair, etc.,

Out of 29 patients who had low T3 syndrome, 19 patients had symptoms suggestive of hypothyroidism accounting for 65.5% and 4 patients among the primary hypothyroidism, all four had symptoms of hypothyroidism which accounts for 100%.

Among 50 patients of CKD, 17 patients did not show any thyroid function abnormalities but out of them 11 had symptoms suggestive of hypothyroidism which accounts for 64.7%.

Features of hypothyroidism such as delayed ankle jerk was present in 2 patients, out of which one were hypothyroid. Wound was found in one patient who is a hypothyroid. 24 hours urinary protein excretion was <1 g/day in all the patients in our study.

Out of 50 patients in our study, 48 patients had anaemia, out of which 2 male and 2 female patients are in normal range.

Table 6 - Analysis Of Thyroid Dysfunction In This Study.

Among the patients 58% had low T3 syndrome, 24% had low T4 syndrome and 8% had primary hypothyroidism.

DISCUSSION

The present study was aimed at to assess the prevalence of thyroid dysfunction in CKD patients. The TSH values in our study ranged from 0.6-8 micro IU/ml. Among 50 patients, 46 patients were in the normal range and 4 patients had high value of more than 20 micro IU/ml. In patients who were in the high range 3 were males and 1 was female.

dysfunction in CKD patients and to determine the correlation between thyroid dysfunction and severity of renal disease. Various studies was conducted about thyroid dysfunction and severity of CKD and shown different results. In our study, CKD patients only on conservative management were studied. This is because thyroid profile undergoes changes due to dialysis independent of that due to chronic kidney disease. Dialysis also changes the previous serum thyroid hormone status in patients with renal failure. Various studies have been studied by comparing CKD patients on conservative management and patients on HD by Ramirez and Kayima et al.

CONCLUSION

- In our study population, 50 CKD patients who were on conservative management were studied. Among them 68% of the patients had low T3 values.
- The change in the serum levels of T3 and T4 in patients with CKD can be considered as being protective, promoting conservation of protein.
- There is progressive increase in the number of patients with Low T3 and T4 syndrome with the severity of renal failure.
- There is increase in incidence of hypothyroidism in patients with chronic kidney disease.
- Excluding hypothyroidism T3 level is found to be low in 58% of the patients and T4 level is low in 24% of the patients.
- As the age increases there is increase in incidence of Low T3 syndrome in patients with CKD.
- In patients with low GFR the serum T3 level was found to be decreased. This shows a direct linear relationship between GFR and T3 level.

Limitations Of This Study

Thyroid dysfunction was studied in patients with CKD irrespective of the etiology of CKD therefore individual correlation of the etiology of CKD with thyroid dysfunction could not be studied. Thyroid dysfunction was not studied in patients on dialysis, as dialysis itself affects the thyroid profile independently of CKD.
