INTRODUCTION
Jaundice occurs in 80% of preterm and 60% of term babies. Bilirubin encephalopathy is one of the main causes for the neurological manifestations like chorea, ataxesis later in life. 60 % of term newborns are afflicted with jaundice in the first week of their birth (1). Phototherapy is one of the most reliable, safe methods to treat hyperbilirubinemia and prevent complications like kernicterus. It lowers the serum bilirubin level by transforming bilirubin into water-soluble isomers that can be eliminated without conjugation in the liver (2, 3). Phototherapy may lead to complications including skin rash, diarrhea, hyperthermia, chills, dehydration, DNA damage to lymphocytes, retinal degeneration, bronze baby syndrome especially in cholestatic jaundice and PDA opening in LBWs and hypocalcaemia (4).

There are several theories to explain the effect of phototherapy on calcium metabolism. Phototherapy leads to inhibition of pineal gland via transcranial illumination, resulting in a decline in melatonin level which stimulates secretion of corticosterone and reduces calcium absorption by bones, as a result, hypocalcaemia develops (5). Since hypocalcaemia is accompanied by a decrease in serum melanin concentration, this effect can be prevented by shielding the occiput with head cap (6). In this present study we examine the effect of head cover on the prevalence of hypocalcaemia.

MATERIALS AND METHODS
This single blind randomized controlled trial was done in Neonatal Intensive Care Unit of Government Kilpauk Medical College and Hospital, Chennai 10, during June 2014 to December 2014. The total sample size was 150 and the study group was divided into Group A (n = 75) Phototherapy without head covered and Group B (n = 75) Phototherapy with head covered with cap. The serum calcium level of each newborn was tested at baseline and 48 hours after phototherapy.

Methods: This single blind randomized controlled study, with 150 term neonates admitted in NICU at GKMC, for a period of six months. The study group was divided into Group A and Group B with 75 each. Group A underwent Phototherapy without head cap (Control) and Group B underwent Phototherapy with head covered with cap (Intervention). The serum calcium level of each newborn was tested at baseline and 48 hours after phototherapy.

Results: Out of 75 neonates in group A 34 had serum total calcium less than 7mg/dl (hypocalcaemia), whereas in group B only 15 had serum total calcium less than 7mg/dl.

Conclusion: Simple intervention like covering the head of neonates with cap reduces the incidence of hypocalcaemia.

REFERENCES
HyPOCALCEMIA: Total calcium < 7mg/dl, ionized calcium < 4 mg/dl.

RESULTS
A total of 1:50 neonates were included in this study. They were divided into two groups of 75 each. The mean weight and age of the neonates were 2.49±0.52, 2.51±0.51 kilograms and 4.63±0.91, 4.45±0.89 days in Group A and Group B respectively. The male and female ratio was 1:2.1. The average time of phototherapy was three days (range: 3-5 days). The peak bilirubin level in both the groups were 16.5±1.95mg/dl and 16.4±1.97mg/dl in Group A and Group B respectively.

INTRODUCTION
Jaundice occurs in 80% of preterm and 60% of term babies. Bilirubin encephalopathy is one of the main causes for the neurological manifestations like chorea, ataxesis later in life. 60 % of term newborns are afflicted with jaundice in the first week of their birth (1). Phototherapy is one of the most reliable, safe methods to treat hyperbilirubinemia and prevent complications like kernicterus. It lowers the serum bilirubin level by transforming bilirubin into water-soluble isomers that can be eliminated without conjugation in the liver (2, 3). Phototherapy may lead to complications including skin rash, diarrhea, hyperthermia, chills, dehydration, DNA damage to lymphocytes, retinal degeneration, bronze baby syndrome especially in cholestatic jaundice and PDA opening in LBWs and hypocalcaemia (4).

There are several theories to explain the effect of phototherapy on calcium metabolism. Phototherapy leads to inhibition of pineal gland via transcranial illumination, resulting in a decline in melatonin level which stimulates secretion of corticosterone and reduces calcium absorption by bones, as a result, hypocalcaemia develops (5). Since hypocalcaemia is accompanied by a decrease in serum melanin concentration, this effect can be prevented by shielding the occiput with head cap (6). In this present study we examine the effect of head cover on the prevalence of hypocalcaemia.

MATERIALS AND METHODS

Thus covering the head of newborns during phototherapy causes significant lesser degree of fall in both total and ionized serum calcium level.

HYPOCALCEMIA BASED ON TOTAL SERUM CALCIUM FOLLOWING PHOTOTHERAPY

Out of 75 neonates in group A, 34 had serum total calcium less than 7mg/dl (hypocalcaemia), whereas in group B only 15 had serum total calcium less than 7mg/dl.

TABLE 3

</tbody>
</table>

Using head cover, in group B reduced the incidence of hypocalcaemia, based on total serum calcium significantly.

HYPOCALCEMIA BASED ON THE SERUM IONISED CALCIUM FOLLOWING PHOTOTHERAPY

Out of 75 neonates in Group A, 37 had serum ionized calcium less than 4mg/dl (hypocalcaemia), compared to 14 in group B.

</tbody>
</table>

Thus using head cover reduces the incidence of hypocalcaemia based on total and ionized serum calcium.

DISCUSSION

Before Phototherapy, the difference between the serum calcium levels between two groups was not statistically significant. Following phototherapy of 48 hours duration the mean serum total calcium was 8.57 ± 1.64mg/dl and 9.57 ± 1.52mg/dl in group A and group B respectively. The mean ionized calcium was 4.2 ± 0.38mg/dl and 4.36 ± 0.30mg/dl respectively in group A and group B respectively (Table 2). Our study shows that there was a significant fall in the serum calcium level. This proves that phototherapy causes hypocalcaemia.

The fall was less in group B compared to group A. There is a definite association between covering the head with cap and the mean serum calcium levels, following phototherapy. This indicates that covering the head of neonates, helps in reducing the prevalence of hypocalcaemia. These findings were consistent with that obtained by Nouh et al.15.

In group A 34 (45.3%) neonates out of 75 had serum calcium <7mg/dl, whereas in group B it was 15 (20%) neonates (Table 3). Thus there is a statistical significant difference between the incidences of hypocalcaemia based on total serum calcium between the groups. P value 0.002 (<0.05). This proves that covering the head of neonates during phototherapy reduces the incidence of hypocalcaemia. In study conducted by Nouh et al incidence of hypocalcaemia in those without head cover was 29%, while incidence of hypocalcaemia in those with head cover was 15.6% values were slightly lesser than that observed in our study.

In group A 37 (49.3%) neonates and in group B 14 (18.7%) neonates had hypocalcaemia based on serum ionized calcium (Table 4). Based on the statistical results there was significant difference in the association of hypocalcaemia between the two groups. P value 0.021(<0.05). It was found that incidence of hypocalcaemia is lesser in those with their heads covered, than in those without their head cover.

In our study we observed a lesser incidence of hypocalcaemia with head cap (Group B). These results were consistent with study conducted by Ehsanipour et al15, where the incidence of hypocalcaemia in term neonates without the head cover was 77.7%, incidence of hypocalcaemia in those with head cover was 22.2%, in our study incidence was much lower. In a study conducted by In Rajesh et al11 study, 2011, observed a significant fall in ionized calcium level in 66.6% of term and 80% of preterm newborns in the study group. In Fatemeh Hajiv7 study, the results were 15 neonates (7.5%) developed hypocalcaemia. Similarly in Karamifar’s14 study, 8.5% of term neonates had hypocalcaemia. In another study, Arora S et al, study10 showed that out of 56 term newborn, 30 (56%) developed hypocalcaemia which were consistent with our results. All these studies proves the protective role of head cap in prevention of phototherapy induced hypocalcaemia.

None of the infants developed severe complications of hypocalcaemia. 2 of hypocalcaemia term babies had symptoms of jitteriness. They were treated with supplemental calcium. Other hypocalcaemia neonates were treated with supplemental calcium. Their serum calcium was followed up to confirm normal values. Other side effects of phototherapy like skin rash was seen in around 10% neonates. Fever was present in around 30% of neonates. Some had loose stools.

LIMITATION OF STUDY

Other factors influencing serum calcium levels like serum albumin, magnesium levels was not studied. These factors may influence serum calcium levels. Future studies may need to take into account these factors.

CONCLUSION

Thus phototherapy induced hypocalcaemia in icteric neonates can be prevented by simple intervention like covering the head of neonates with cap.
