DISCUSSION

Study showed an impaired quality of life among 115 COPD cases using St. George's respiratory questionnaire (SGRQ). Quality of life was low in all the domains as compared to healthy subjects. However, activity domain was the most affected while impact domain was least affected. Mean total score for SGRQ in the patients was 36.14±18.50. Ahmed et al also showed impairment of QOL across all domains.[7] Symptom domain was found to be most affected while impact domain was the least affected. Negi et al also found marked impairment of HRQL.[8] When compared to studies done in other countries, it was found that Indian COPD patients suffer somewhat same reduction in QOL as from other countries.[9,10]

Socio-demographic variables such as age, sex, socioeconomic status and occupation were not found to have significant effect on quality of life in COPD patients in the present study. Previous studies have shown varied results in this regard.[11,12] Other studies also reported no correlation between age and QOL while some have reported worsening of SGRQ scores with increasing age.[13,14]

Patients with poor socioeconomic status while in this study; socioeconomic status was not found to be significantly associated with impaired QOL concurrent with other studies.

Smoking was found to have significant impact on QOL in the present study. Other studies also reported that smoking significantly affects QOL in COPD patients.[8-10] Findings were concurrent with other researcher with regard to pack years of smoking, passive smoking and patterns of use of biomass fuel especially in females.[4]

BMI was not found to have significant impact on QOL in the present study. This was Concordant with other studies where underweight patients have worse health status than patients of normal weight; other reported no association found in their study while some have shown that being underweight or obese to be consistently associated with worse HRQOL as compared to normal weight patients.. Spirometry was done at the time of the study to assess the severity of the disease.[12-14]

CONCLUSION

Poor quality of life in COPD patients, a slowly progressing disease with no specific cure, is cause of concern, public health programme should focus more on preventable aspects of quality of life. Smoking, exposure to smoke/dusty / chemical vapors & family history of COPD are main determinant of COPD. Public health planners should concentrate to mitigate these causes.
