Profile of Osteoarthritis Patient Attending Tertiary Care OPD: A Cross-Sectional Study

ABSTRACT

Background:- Knee osteoarthritis is a chronic medical condition of public health importance in this setting. It is mostly diagnosed when preventive measures are no longer practicable due to reliance on the radiological diagnosis. Methods:- The present study was carried out in people’s college of medical sciences and research centre, Bhopal from November 2012 – April 2014. The study consisted of 25 patients out of which 8 patients had bilateral involvement so in total 33 knees were included in our study. It was a cross-sectional study. Results:- Of 33 knees of 25 patients (8 with bilateral involvement) were studied in the department of orthopedics. Out of 25 patients there were 6 males and 19 females. Subject classified according to stage of kellegren, out of 33 knees of 25 subject (8 bilateral), 14 were in stage II and 19 were in stage III, there was no statistically significant difference among male and female in respect to stages of kellegren. Conclusion:- Females were affected more than male with OA. Most of the subjects were affected in their late fifties. Female were affected in earlier age group than males. Right side knee was significantly more affected than affected left knee.

Kellegren classification, Knee, Osteoarthritis, Profile

Introduction

Osteoarthritis is the most common joint disease, and is characterized by progressive loss of articular cartilage, subchondral bone sclerosis, osteophyte formation, synovial membrane changes, and an increase in synovial fluid with decreased viscosity and lubrication properties. Mechanical, biochemical, and genetic factors are all involved in pathogenesis of osteoarthritis. Structural, synovitis, progressive articular cartilage loss, osteophyte formation and subchondral sclerosis, generally in weight bearing joints such as knee and hip, give rise to biomechanically unstable joints that result in loss of function. Clinically, patients with OA experience pain, stiffness, loss of motion, weakness, and joint instability, all leading to functional limitation and disability. Perhaps the earliest descriptions of OA were provided by Heberden and Haygarth in the 19th century. In the 1930s and 1940s, Stecher showed that there were two forms of this disease, idiopathic and post traumatic. The first x-ray grading system was developed in the 1950s by Jonas Kellgren and John Lawrence.

Methodology

The present study was carried out in people’s college of medical sciences and research centre, Bhopal from November 2012 – April 2014. The study consisted of 25 patients out of which 8 patients had bilateral involvement so in total 33 knees were included in our study. It was a cross-sectional study. The permission form the institutional ethical committee was sought. All patients with knee pain presented in Orthopaedic OPD were screened clinically, Radiologically (AP & lat in standing position) and Pathological investigations was done. Those were found eligible for the study were explained about the study. After obtaining their willingness a written explained consent in the patients own language which he or she can read and write Or in case of an illiterate his left thumb impression in the presence of an attendant who can both read and write was taken. After screening the grade of OA was ascertained according to Kellegren and Lawrence classification of osteoarthritis.

Statistical analysis

The data was entered in Microsoft office excel 2007. The data was analyzed using Epi-info software. The continuous variable was analyzed using mean and standard deviation while categorical data as percentage and proportion.

Results

Of 33 knees of 25 patients (8 with bilateral involvement) were studied in the department of orthopedics. Out of 25 patients there were 6 males and 19 females. There was no statistically significant difference in distribution of subject according to age (p-0.3271). Mean age of study subject that is 58.60yrs. There was no statistically significant difference in mean age between male and female (p-0.692). Table no. 1 reveals distribution of study subject according to stage of
Discussion

The present study was conducted in the Department of Orthopedics, People’s college of medical sciences and research centre bhanpur Bhopal from 01-11-2012 to 30-04-2014. In present study, proportion of knee affecting male with OA was 30.3% while in female it was 69.7%. Clinical diagnosis of OA is made in one in three persons over the age of 50 years, and women are more frequently affected than men. OA is the leading cause of chronic disability in the elderly, owing in part to improved longevity. One in two persons over the age of 70 years and over 85% of persons aged 80 years or more have a clinical diagnosis of OA. The most commonly affected joint is the knee, but OA also affects the hip, spine, hands, and feet. Incidence and prevalence vary slightly by the affected area. Women have higher incidence and prevalence of hand and knee OA and men have higher prevalence of hip OA. Both the incidence (number of new cases in a specific period of time) and prevalence (the number of cases in a population at a given time) of OA increase in the elderly. A common initiating factor in OA is the inability of the joint to repair mechanical (trauma) or metabolic (obesity) injuries during which cellular and biochemical pathways, including immune responses, are activated for tissue repair. Immunoscience, which cellular and biochemical pathways, including immune

OA.16 Both the incidence (number of new cases in a specific period of time) and prevalence (the number of cases in a population at a given time) of OA increase in the elderly.17 A common initiating factor in OA is the inability of the joint to repair mechanical (trauma) or metabolic (obesity) injuries during which cellular and biochemical pathways, including immune responses, are activated for tissue repair. Immunoscience, therefore, may be an important factor in promoting pathogenesis of OA in the elderly. Similar findings were noted in the present study. The pathogenesis of OA involves interactions of joint tissues, joint biomechanics, and biochemical pathways. The predominant pathological features of OA are synovitis and fibrosis, accelerated bone remodeling with osteoarthropathy development, and articular cartilage degeneration. Genetic defects of connective tissue structural and regulatory proteins, such as bone morphogenetic protein 2 (BMP2), cartilage intermediate layer protein (CILP), frizzled related protein (FRZB), and TNF alpha-induced protein (TNFALP6) have been clearly implicated in the development of OA and are often associated with increased risk of OA.20-21

Conclusion

Females were affected more than male with OA. Most of the subjects were affected in their late fifties. Female were affected in earlier age group than males. Right side knee was significantly more affected than affected left knee.
