Introduction
Mucinous cystadenomas make up 15% - 20% of all ovarian tumors. They often become very large and can extend up into the abdomen. About 80% of mucinous tumors are benign, 10% are borderline and 10% are malignant. Although benign ovarian mucinous tumors are rare at the extremities of age, before puberty and after menopause, they are common between the third and the fifth decades. The most frequent complications of benign ovarian cysts, in general, are torsion, hemorrhage and rupture. Pseudomyxoma peritonei can result if the tumor ruptures and spills its contents into the abdomen. This report presents a case of a large ovarian mucinous cystadenoma in an Indian adolescent girl.

Case Report
A 15 years old girl presented to our outpatient department with a history of progressive abdominal distension from 5 months and respiratory discomfort since a month. On clinical examination patient was emaciated, abdomen was grossly distended, making overlying skin thin and veins distended & prominent, massive ascites with obvious fluid thrill. A football size mass occupying the lower abdomen, more towards left side was present. Ultrasound revealed left side large ovarian cyst with massive ascites. Patient was counselled and signed information for surgical exploration.

Under spinal anaesthesia, an initial midline subumbilical incision was made and 12 litres of yellowish mucinous fluid was suctioned. A huge cystic mass was noticed arising from the left ovary. Later on, the incision was extended up, about 5 cm below xiphisternum, to deliver the cystic mass intact without exposed it to the risk of rupture intraperitoneally. The outer surface of the mass was smooth and intact all-around without external growths or adhesions. The uterus, right adnexa, and appendix were looking healthy. An abdominal drain was placed in situ for 6 days. The post-operative period was uneventful. Biopsy report revealed benign mucinous cystadenoma.

Discussion
There are four major categories of ovarian tumors:
1) Epithelial tumors (65% - 75%) — serous or mucinous cystadenoma/carcinoma, clear cell carcinoma, Brenner tumor;
2) Germ cell tumors (15%) — dysgerminoma, embryonal cell cancer, choriocarcinoma, teratoma;
3) Sex-chord-stromal tumors (5% - 10%) — granulosa cell tumor, thecoma, fibroma;
4) Metastatic tumors (10%) — uterine, stomach, colon, breast, lymphoma.

These tumors are usually evaluated using ultrasound, CT scan, or MRI. Findings on imaging studies are nonspecific. These ovarian tumors may be multi-septated, cystic masses with thin walls. They
may contain varying amounts of solid tissue which consists of proliferating stromal tissue, papillae, or malignant tumor cells. Tumour markers may also aid us in telling us the origin of the tumour. Mucinous cystadenomas are divided into three categories: benign, borderline, and malignant. Survival is largely dependent on the histology of the tumor. 10 year survival rate of 100% for benign tumors, 60% for borderline tumors, and only 34% for the malignant subtype. Benign mucinous tumors can often be seen at an early stage. Benign mucinous cystadenomas comprise 80% of mucinous ovarian tumors and 20% - 25% of benign ovarian tumors overall. The peak incidence occurs between 30 - 50 years of age. Benign tumors are bilateral in 5% - 10% of cases. Borderline mucinous cystadenomas make up about 10% of mucinous ovarian neoplasms and are bilateral in 10% of cases. Malignant mucinous cystadenomas are rare, and encompass 10% of mucinous ovarian tumors and 5% - 10% of primary malignant ovarian neoplasms overall. They are bilateral in 15% - 30% of cases and have a peak incidence between 40 - 70 years of age. Giant ovarian tumors have become rare in current medical practice, as most cases are discovered early during routine check-ups. Detection of ovarian cysts causes considerable worry for women because of fear of malignancy, but fortunately the majority of ovarian cysts are benign. These giant tumors may be associated with pressure symptoms, urinary tract changes, respiratory embarrassment and debilitation. While operating on such tumors care has to be taken to manage these complications as well as the problems associated with sudden decompensation of such large tumors. Histologically, mucinous cystadenoma is lined by tall columnar non-ciliated epithelial cells with apical mucin and basal nuclei. 80% tumors are cystadenomas while the remaining 20% is of the borderline variety, noninvasive (intraglandular; intraepithelial) carcinomas, or invasive carcinomas. The borderline tumors may be of intestinal type or mullerian (endocervical-like) type. The intestinal-type tumors are by far the most common. Mucinous cystadenoma is a benign ovarian tumor. It is reported to occur in middle-aged women. It is rare among adolescents or in association with pregnancy. On gross appearance, mucinous tumors are characterized by cysts of variable sizes without surface invasion. Only 10% of primary mucinous cystadenoma is bilateral. In our case, the tumor was unilateral, affecting the left ovary. The cyst was filled with sticky gelatinous fluid rich in glycoprotein. Management of ovarian cysts depends on the patient’s age, the size of the cyst and its histopathological nature. Conservative surgery as ovarian cystectomy and salpingo-oophorectomy is adequate for benign lesions.

Conclusions

Management of ovarian cysts depends on the patient’s age, the size of the cyst and its histopathological nature. Conservative surgery as in ovarian cystectomy and salpingo-oophorectomy is adequate for benign lesions. For large ovarian masses with a risk of malignancy we suggest laparotomy and intraoperatively to follow the oncologic protocols, which included careful intraperitoneal exploration and a biopsy of the diaphragm, the omentum majus, the Pouch of Douglas and right and left side colon douche. The histopathologic workup of our case revealed a mucinous cystadenoma.

This disease has a significant biological/physiological and psychological impact on the patient as described above and for these reasons we suggest a multidisciplinary approach so that the collaboration of different specialists can create the optimal conditions to manage the perioperative period by trying to minimize the risk of the complications.
